

Apple Stock Prediction:

- **Open:** The price at which the first trade occurs when the trading period begins.
- **High:** The maximum price reached by the stock at any point during the interval.
- **Low:** The minimum price reached by the stock at any point during the interval.
- **Close:** The final price at which the last trade is executed before the period ends; this is often considered the most critical price for technical analysis.
- **Volume:** The total quantity of shares or contracts traded, which serves to confirm the strength or validity of the price movement indicated by the OHLC data.

Key Takeaways:

- **Price Blew Up Around 2000:** For almost 20 years (1980 to roughly 1998), the price basically hovered low between 0 and 2. Then, around 1998-2000, it shot straight up past 4. This lines up with the classic late-90s dot-com bubble spike.
- **Opening and Closing Prices Move in Lockstep:** The scatter plot forms a practically straight diagonal line. That just means whatever price the stock opens at on a given day, it closes very close to it. Intra-day swings don't change the overall trend much.
- **One Weird Data Outlier:** Up around on the scatter plot, there's a lone dot sitting far away from the rest of the cluster. It looks like either a data glitch, an unadjusted stock split, or a single crazy spike day.

Google Stock Prediction:

Key Takeaways

- **Consistent Long-Term Bull Run (2004-2019):** Starting from late 2004, the value climbed steadily with only minor pauses, picking up serious momentum after 2012 and peaking right around 2019.
- **The "Drop" in 2020 is Incomplete Data:** The steep crash in 2020 isn't a market crash, it's because the date slicer cuts off on **01-04-2020** (April 1, 2020). Because you only have about 3 months of data for 2020 compared to 12 full months for earlier years, the annual total naturally looks way lower.
- **Virtually Identical Open vs. Close:** The scatter plot forms a tight, unbroken 45-degree line from 0 all the way past 1,500, with a few high-value trades reaching up near 2,750. Intraday movement is minimal compared to the overall price level.
- **Wider Variance at Higher Prices:** Most data points clump densely between 0 and 1,500. Above 2,000, points become sparse and spread out, reflecting higher volatility or fewer trading days at those record highs.

Tesla Stock Prediction:

Key Takeaways

- **Massive Growth Surge (2012-2014):** After a quiet start around 2010-2012, the value experienced an explosive multi-fold rally between 2012 and 2014, jumping from under 10K to nearly 60K on the yearly aggregate.
- **Plateau and Peak (2017-2018):** Following a brief dip around 2016, the trend rallied to an all-time peak near 80K across 2017 and 2018 before starting to taper off in 2019.
- **Partial Year Trap in 2020:** Just like the previous dashboard, the drop in 2020 down to ~40K is an artifact of incomplete data. The date filter cuts off on **01-04-2020**, meaning you are comparing only three months of cumulative price data against 12 full months in prior years.
- **High-End Volatility Spread:** While Open and Close track each other tightly along the 45-degree line up to roughly 500, the points become noticeably more scattered and dispersed between 600 and 900, showing higher intra-day price swings during high-value trading days.
